

Two-phase commit

A [transaction](#) spanning multiple Firebird/InterBase® [databases](#) is automatically [committed](#) in two phases. A two-phase commit guarantees that the transaction updates either all of the databases involved or none of them - data is never partially updated.

In the first phase of a two-phase commit, Firebird/InterBase® prepares each database for the commit by writing the changes from each subtransaction to the database. This subtransaction is the part of a multi-database transaction that involves only one database. In the second phase, InterBase® marks each subtransaction as committed in the order that it was prepared.

If a two-phase commit fails during the second phase, some subtransactions are [committed](#) and others are not. A two-phase commit can fail if a network interruption or disk crash makes one or more databases unavailable. Failure of a two-phase commit causes [in limbo transactions](#), i.e. transactions that the server does not know whether to commit or roll back.

It is possible that some records in a database are inaccessible due to their association with a transaction that is in a limbo state.

Note: The [Borland Database Engine \(BDE\)](#), as of version 4.5, does not exercise the two-phase commit or distributed transactions capabilities of Firebird/InterBase®, therefore applications using the BDE never create limbo transactions.
